Conductors → The substance through which electric current can pass are called conductor.

Non-conductors →

[Faraday's law of Electrolysis]

It states that "The amount of any substance liberated from or deposited on the electrode during electrolysis is directly proportional to the quantity of ^{electricity} charge pass through the electrolytic solution."

If m be the mass deposited on or liberated from an electrode & Q be the charge passed through the soln,

Mathematically

$$m \propto Q$$

$$m = z Q$$

$$m = z It$$

$$[Q = It]$$

where,

z = proportionality constant,

Known as ~~electrochemical~~ ^{chemical} equivalent

Quantity of charge passed. & It is

Equal to product of current & time for which the current pass.

$$1F = 96500 \text{ C}$$

Page No. _____

Date: / /

I = current in ampere

Q = charge passed in coulomb

m = mass of substance deposited or liberated in gram.

we have,

$$m = zIt \quad \text{or} \quad z = \frac{m}{It}$$

If one ampere current is passed through the electrolyte for one second, then $m = z$ so, electrochemical equivalent ^{is} defined as the weight of substance deposited or liberated by passage of one ampere current for one second.

Since, 1 Faraday (96500 C) charge deposits one gm equivalent

Let E = equivalent weight of substance then,

96500 coulomb deposits E g substance
1 coulomb $\frac{E}{96500}$ g of substance.

By definition, mass deposited or liberated by one coulomb charge is called electrochemical equivalent. Therefore,

$$z = \frac{E}{96500}$$

we have

$$m = zIt$$

$$m = \frac{EIt}{96500} \quad \text{or} \quad \frac{EQ}{96500}$$

[Faraday second Law]

Date: / /

This law states that "When the same quantity of electricity is passed through different electrolytes connected in series, the amount of substances deposited or liberated from the respective electrodes are proportional to their equivalent weight"

$$m \propto Q$$

$$m = kQ$$

$$m/Q = k \text{ (constant).}$$

Verification,

Let the same quantity of electricity is passed through different voltameters connected in series containing aqueous solution of H_2SO_4 , $CuSO_4$ & $AgNO_3$ as shown in fig.

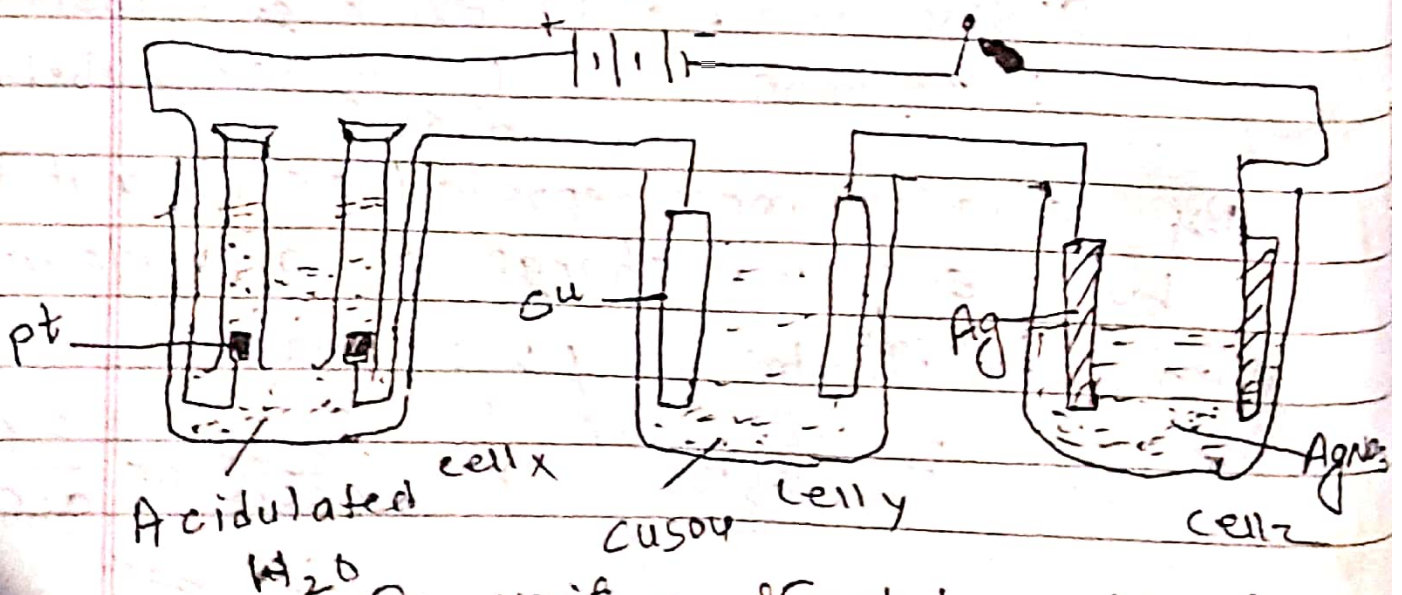

Fig - Verification of Faraday's second Law

The mass of hydrogen, copper & silver deposited at the respective electrodes are in the ratio, of their equivalent weights.

For cell x:

$$\frac{\text{mass of hydrogen deposited or liberated}}{\text{equivalent weight of hydrogen}} = \text{constant} \quad \text{--- (i)}$$

$$\text{For cell y:} \quad \frac{\text{mass of copper deposited}}{\text{eq. wt of copper}} = \text{constant} \quad \text{--- (ii)}$$

$$\text{For cell z:} \quad \frac{\text{mass of silver deposited}}{\text{eq. wt of silver}} = \text{constant} \quad \text{--- (iii)}$$

from eqn (i), (ii) & (iii)

$$\frac{\text{mass of hydrogen displaced}}{\text{eq. wt of hydrogen}} = \frac{\text{mass of copper deposited}}{\text{eq. wt of copper}} = \frac{\text{mass of silver deposited}}{\text{eq. wt of silver}}$$

From the above relation,

$$\frac{\text{mass of hydrogen displaced}}{\text{mass of copper deposited}} = \frac{\text{eq. wt of hydrogen}}{\text{eq. wt of copper}}$$

$$\frac{\text{mass of hydrogen}}{\text{mass of silver}} = \frac{\text{eq. wt of hydrogen}}{\text{eq. wt of silver}}$$

$$\frac{\text{mass of copper}}{\text{mass of silver}} = \frac{\text{eq. wt of copper}}{\text{eq. wt of silver}}$$

An electric current is passed through three cells in series containing respective soln. of CuSO_4 , AgNO_3 , & KI . What weight of silver & Iodine will be liberated while 1.25g of copper is being deposited.

CuSO_4 AgNO_3 KI

1.25g.

50g

$$\frac{\text{wt of copper}}{\text{wt of Iodine}} = \frac{31.7}{127}$$

$$x = 50 \text{ g of Iodine.}$$

$$\frac{\text{wt of copper}}{\text{wt of silver}} = \frac{31.7}{107.8}$$

$$\frac{1.25}{y} = \frac{31.7}{107.8}$$

$$y = 4.25 \text{ g silver}$$

119 0.1978 g of copper is deposited by a current of 0.2 ampere in 50 minutes. What is electrochemical equivalent of copper?

Solⁿ. Given. $t = 50 \text{ min.}$ $50 \times 60 = 3000 \text{ sec.}$

$$I = 0.2 \text{ ampere}$$

$$Q = It = 0.2 \times 3000 = 600 \text{ coulomb}$$

Amount of copper deposited by 600 coulomb = 0.1978 g
~~1600 coulomb deposited.~~

$$\text{" " " " " " 1 coulomb} = \frac{0.1978}{600}$$

$$= 0.0003296 \text{ gm}$$

Electrochemical of Cu = 0.0003296 g
